## The Fee Effects of the 2014 EU Auditing Reforms:

## A first glance

## Abstract

I test whether the implementation of the EU audit reforms has had an effect on audit and non-audit fees. I use European clients listed on exchange-regulated equity markets as my control group. An analysis based on the full sample suffers from lack of common support between treatment and control groups and produces inconsistent findings. Limiting the sample to clients of comparable size by within country-year-industry bin propensity score matching, I document an insignificant negative effect of the EU audit regulation on audit fees and an economically large and marginally significant negative effect on non-audit fees. I urge the reader to apply caution when interpreting my findings as they are sensitive to the matching procedure, rely on an unverified client exchange classification by Audit Analytics and are based on a small sub-sample of client data for the matched analysis, meaning that they represent a local average treatment effect for small publicly listed clients at best.

The data is obtained from Audit Analytics EU as provided by WRDS. Countries with less than 1,000 observations are excluded. The sample covers the periods 2009 to 2020 and 4,480 unique clients form 10 countries. For audits involving multiple audit firms audit fees are aggregated at the client-fiscal year level so that Audit fees (Non-audit fees) represent the (non) audit fees that the client incurred during a fiscal year. Assets and Market Capitalization are client values and measured at the fiscal year end. Revenues represents client net sales during the fiscal year. All values are measured in Mio. Euro.  $Big \not 4$  is a binary variable taking the value of one whenever a Big 4 auditing firm (KPMG, PWC, EY or Deloitte) is involved in the audit. The treatment group comprises clients that are listed on EU-regulated markets while the control group comprises clients that are listed on exchange-regulated markets.

Table 2: Correlations (Full Sample)

|                              | A    | В    | С    | D    | Е    | F    |

The data is obtained from Audit Analytics EU as provided by WRDS. To establish covariate balance between treatment and control observations, data are matched within country, year and Fama French 12 industry bins by logged values of size, revenue and market capitalization as well as a big 4 dummy. At least 50 obvservations with a minimum of 10 observations per group are required for each bin. Matching is done based on logit propensity scores without replacement and a caliper of 0.05. The sample covers the periods 2009 to 2020 and 1,135 unique clients form 3 countries. For audits involving multiple audit firms audit fees are aggregated at the client-fiscal year level so that Audit fees (Non-audit fees) represent the (non) audit fees that the client incurred during a fiscal year. Assets and Market Capitalization are client values and measured at the fiscal year end. Revenues represents client net sales during the fiscal year. All values are measured in Mio. Euro. Big 4 is a binary variable taking the value of one whenever a Big 4 auditing firm (KPMG, PWC, EY or Deloitte) is involved in the audit. The treatment group comprises clients that are listed on EU-regulated markets while the control group comprises clients that are listed on exchange-regulated markets.

Notes: This table presents the results of four OLS regressions regressing (non) audit fees on our treatment indicators and additional covariates. The sample and all variables are as defined in Table 4. Standard errors are presented in parentheses below the coefficients. \*/\*\*/\*\*\* indicate two-sided significance levels below 10/5/1 %, respectively.
